

# 要点

- regularization + memorization effect
- 详细分析了memorization effect 的形成过程
- 运用semi-supervised 的方法设计出了有记忆性的正则化
- 用了该方法后就不用early stopping，网络会抑制wrong label的fitting

# 方法

## 模型的memorization effect

**Theorem 1 (Informal).** Denote by  $\{\Theta_t\}$  the iterates of gradient descent with step size  $\eta$ . For any  $\Delta \in (0, 1)$ , there exists a constant  $\sigma_\Delta$  such that, if  $\sigma \leq \sigma_\Delta$  and  $p/n \in (1 - \Delta/2, 1)$ , then with probability  $1 - o(1)$  as  $n, p \rightarrow \infty$  there exists a  $T = \Omega(1/\eta)$  such that:

- **Early learning succeeds:** For  $t < T$ ,  $-\nabla \mathcal{L}(\Theta_t)$  is well correlated with the correct separator  $\mathbf{v}$ , and at  $t = T$  the classifier has higher accuracy on the wrongly labeled examples than at initialization.
- **Gradients from correct examples vanish:** Between  $t = 0$  and  $t = T$ , the magnitudes of the coefficients  $(\mathcal{S}(\Theta_t \mathbf{x}^{[i]})_c - \mathbf{y}_c^{[i]})$  corresponding to examples with clean labels decreases while the magnitudes of the coefficients for examples with wrong labels increases.
- **Memorization occurs:** As  $t \rightarrow \infty$ , the classifier  $\Theta_t$  memorizes all noisy labels.

从线性模型的损失函数可以定性证明以上结论（S为softmax）

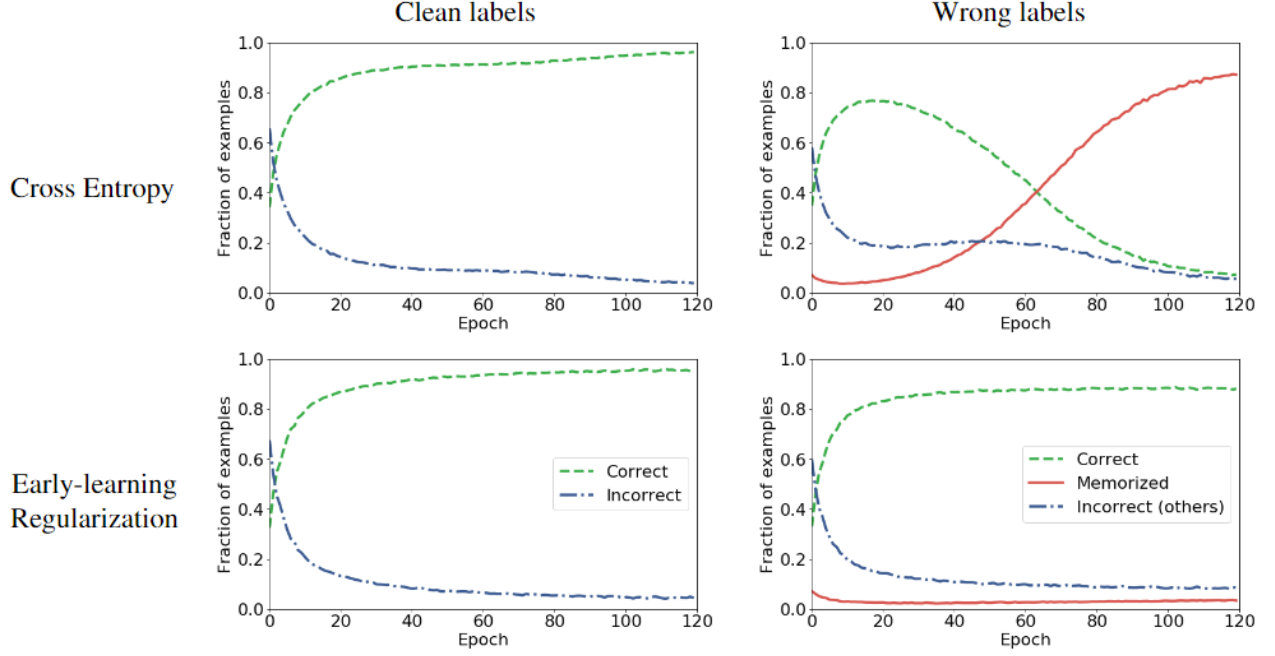

$$\min_{\Theta \in \mathbb{R}^{2 \times p}} \mathcal{L}_{\text{CE}}(\Theta) := -\frac{1}{n} \sum_{i=1}^n \sum_{c=1}^2 \mathbf{y}_c^{[i]} \log(\mathcal{S}(\Theta \mathbf{x}^{[i]})_c),$$
$$\nabla \mathcal{L}_{\text{CE}}(\Theta)_c = \frac{1}{n} \sum_{i=1}^n \mathbf{x}^{[i]} \left( \mathcal{S}(\Theta \mathbf{x}^{[i]})_c - \mathbf{y}_c^{[i]} \right),$$

分析真实类别是c的clean label和wrong label，clean label 占多数

- 1.当训练早期， $\Theta$ 还没有与 $\mathbf{v}$ 相关联时， $\mathcal{S}(\Theta \mathbf{x}_c^{[i]}) - \mathbf{y}_c^{[i]}$ 对于任何样本都很大的，因此 $\nabla L_c$ 大致指向全体样本的平均方向，也就是简单模式
- 2.当 $\Theta$ 与 $\mathbf{v}$ 相关联时，此时正确标签的梯度可以忽略，因此错误标签的梯度开始起主导作用，同时错误标签的梯度会指向正确梯度的垂直方向，最终记住noisy label。注意此时并不会影响clean label的梯度消失。

$$\nabla \mathcal{L}_{\text{CE}}(\Theta) = \frac{1}{n} \sum_{i=1}^n \nabla \mathcal{N}_{\mathbf{x}^{[i]}}(\Theta) \left( \mathbf{p}^{[i]} - \mathbf{y}^{[i]} \right),$$

对于神经网络亦然。并且可以发现，梯度主要受限于  $p^{[i]} - y^{[i]}$

## 正则化项

因此，根据之前的分析。我们的目标是：第二阶段正确标签的梯度不消失，仍然起主导作用

Figure 2: Illustration of the effect of the regularization on the gradient of the ELR loss (see Lemma 2) for the same deep-learning model as in Figure 1. On the left, we plot the entry of  $\mathbf{p}^{[i]} - \mathbf{y}^{[i]} + \lambda \mathbf{g}^{[i]}$  corresponding to the true class, denoted by  $c^*$ , for training examples with clean (blue) and wrong (red) labels. The center image shows the  $c^*$ th entry of the cross-entropy (CE) term  $\mathbf{p}^{[i]} - \mathbf{y}^{[i]}$  (dark blue) and the regularization term  $\mathbf{g}^{[i]}$  (light blue) separately for the examples with clean labels. During early learning the CE term dominates, but afterwards it vanishes as the model learns the clean labels (i.e.  $\mathbf{p}^{[i]} \approx \mathbf{y}^{[i]}$ ). However, the regularization term compensates for this, forcing the model to continue learning mainly on the examples with clean labels. On the right, we show the CE and the regularization term (dark and light red respectively) separately for the examples with wrong labels. The regularization cancels out the CE term, preventing memorization. In all plots the curves represent the mean value, and the shaded regions are within one standard deviation of the mean.

$$\mathcal{L}_{\text{ELR}}(\Theta) := \mathcal{L}_{\text{CE}}(\Theta) + \frac{\lambda}{n} \sum_{i=1}^n \log \left( 1 - \langle \mathbf{p}^{[i]}, \mathbf{t}^{[i]} \rangle \right).$$

**Lemma 2** (Gradient of the ELR loss). *The gradient of the loss defined in Eq. (6) is equal to*

$$\nabla \mathcal{L}_{\text{ELR}}(\Theta) = \frac{1}{n} \sum_{i=1}^n \nabla \mathcal{N}_{\mathbf{x}^{[i]}}(\Theta) \left( \mathbf{p}^{[i]} - \mathbf{y}^{[i]} + \lambda \mathbf{g}^{[i]} \right) \quad (7)$$

where the entries of  $\mathbf{g}^{[i]} \in \mathbb{R}^C$  are given by

$$\mathbf{g}_c^{[i]} := \frac{\mathbf{p}_c^{[i]}}{1 - \langle \mathbf{p}^{[i]}, \mathbf{t}^{[i]} \rangle} \sum_{k=1}^C (\mathbf{t}_k^{[i]} - \mathbf{t}_c^{[i]}) \mathbf{p}_k^{[i]}, \quad 1 \leq c \leq C. \quad (8)$$

这个是N是雅可比矩阵，但是他给的是x对于theta求导的雅可比矩阵，一般都是theta对于x求导的矩阵

$$\mathbf{t}^{[i]}(k) := \beta \mathbf{t}^{[i]}(k-1) + (1 - \beta) \mathbf{p}^{[i]}(k),$$

加入这个正则化项后：

early learning时 $t_{c^*}$ 为主导地位，因此 $g_{c^*}$ 为负。

随着clean label 的 $p_{c^*}$ 越来越大， $g_{c^*}$ 更小，抑制了clean label的继续学习。虽然一定程度上抑制了，但是多个clean label的梯度之和仍能占据主要地位。

wrong label的 $p_{c^*}$ 在memorization effect之前都是接近于0，因此 $t_{c^*}$ 几乎为0， $g_{c^*}$ 为正，一定程度上“骗过了”损失函数。

## 加入一些trick的强化模型ELR+

**return**  $\Theta_1, \Theta_2$

---

1. 双网络训练，权重平均后预测
2. 网络的权重也采用 temporal ensembling
3. mixup data augmentation:

To apply *mixup* data augmentation, when processing the  $i$ th example in a mini-batch  $(\mathbf{x}^{[i]}, \mathbf{y}^{[i]}, \mathbf{t}^{[i]})$ , we randomly sample another example  $(\mathbf{x}^{[j]}, \mathbf{y}^{[j]}, \mathbf{t}^{[j]})$ , and compute the  $i$ th mixed data  $(\tilde{\mathbf{x}}^{[i]}, \tilde{\mathbf{y}}^{[i]}, \tilde{\mathbf{t}}^{[i]})$  as follows:

$$\begin{aligned}\ell &\sim \text{Beta}(\alpha, \alpha), \\ \ell' &= \max(\ell, 1 - \ell), \\ \tilde{\mathbf{x}}^{[i]} &= \ell' \mathbf{x}^{[i]} + (1 - \ell') \mathbf{x}^{[j]}, \\ \tilde{\mathbf{y}}^{[i]} &= \ell' \mathbf{y}^{[i]} + (1 - \ell') \mathbf{y}^{[j]}, \\ \tilde{\mathbf{t}}^{[i]} &= \ell' \mathbf{t}^{[i]} + (1 - \ell') \mathbf{t}^{[j]},\end{aligned}$$
