

要点

- 噪声建模+simultaneous update on CM and base classifier & annotators
- 加入基于每个annotator的 $trace(CM)$ 最大化的正则项
- 这种方法在1 label per image的情况下表现良好

方法

假设base CNN classifier 输出的 \hat{y} 和 y 的CM为 P ; 每个标注者的CM为 \hat{A}^r . 那么联合训练可以得到 $P \hat{A}^r \rightarrow A^r$

本文证明了: 若 $trace(\hat{A}^r)$ 达到最大, 那么就可以收敛到 A^r . 前提是 A^r 和 \hat{A}^r 必须为diagonal dominant

A 初始化为identity matrix

实验

噪声种类汇总

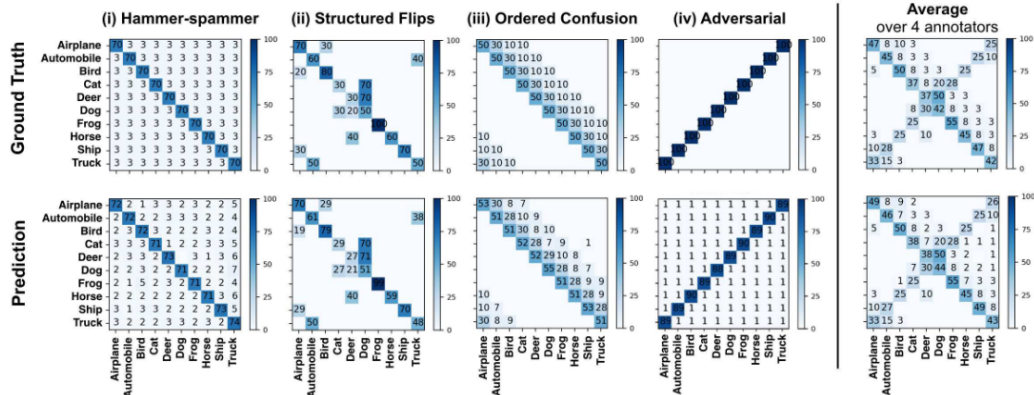

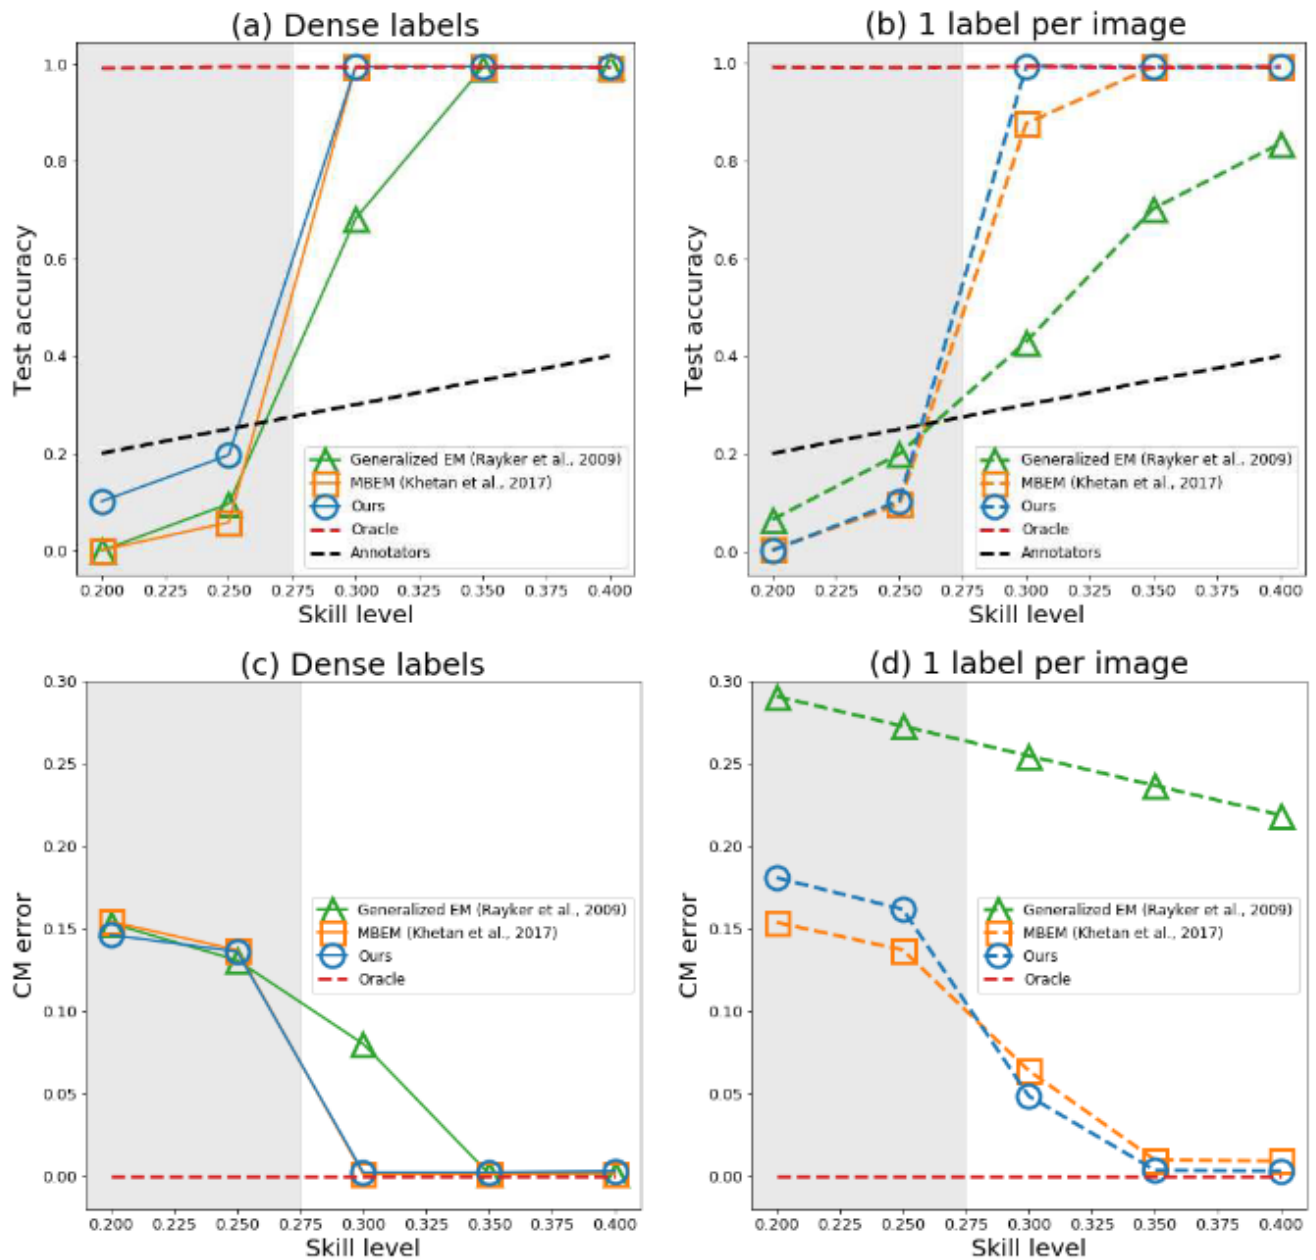

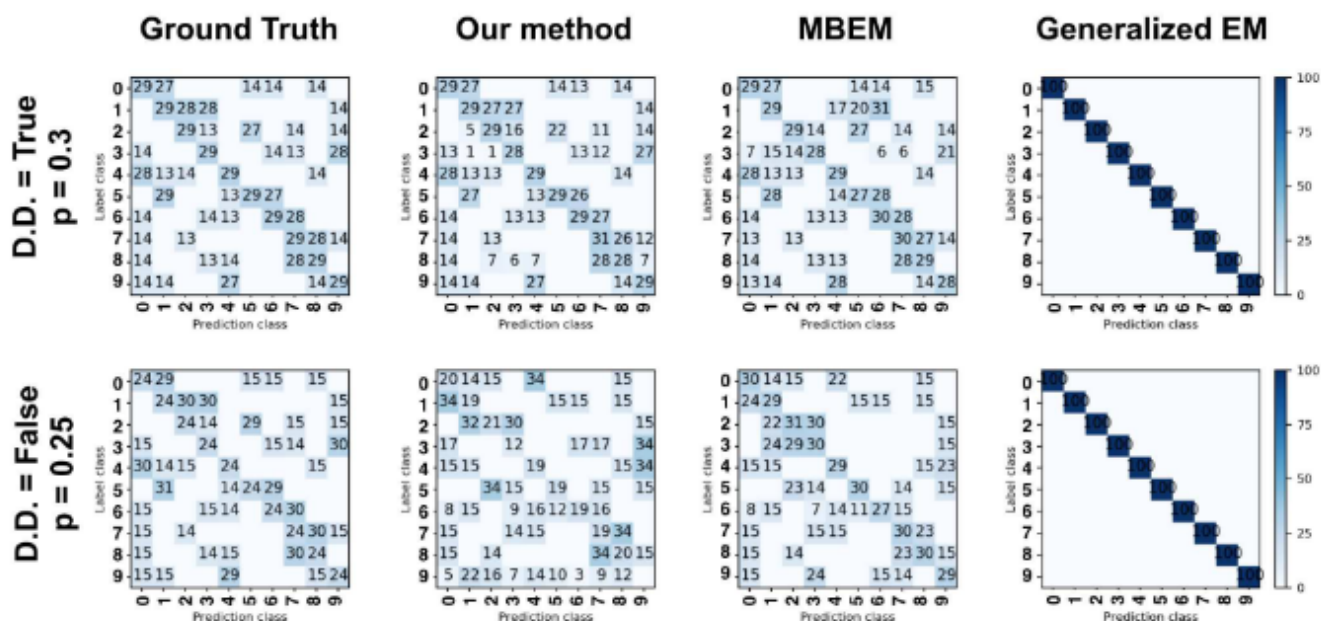

Figure 2: A diverse set of 4 simulated annotators on CIFAR-10. The top row shows the ground truths while the bottom row are the estimation from our method, trained with only one label per image.

实验1：模型在dense label和1 label per image情况下的效果

CM error是指：真CM和预测CM的Frobenius norm

实验2：模型对超参数的敏感性

T指总的EM次数，G指每次M步梯度下降的次数

实验3：模型的抗噪能力

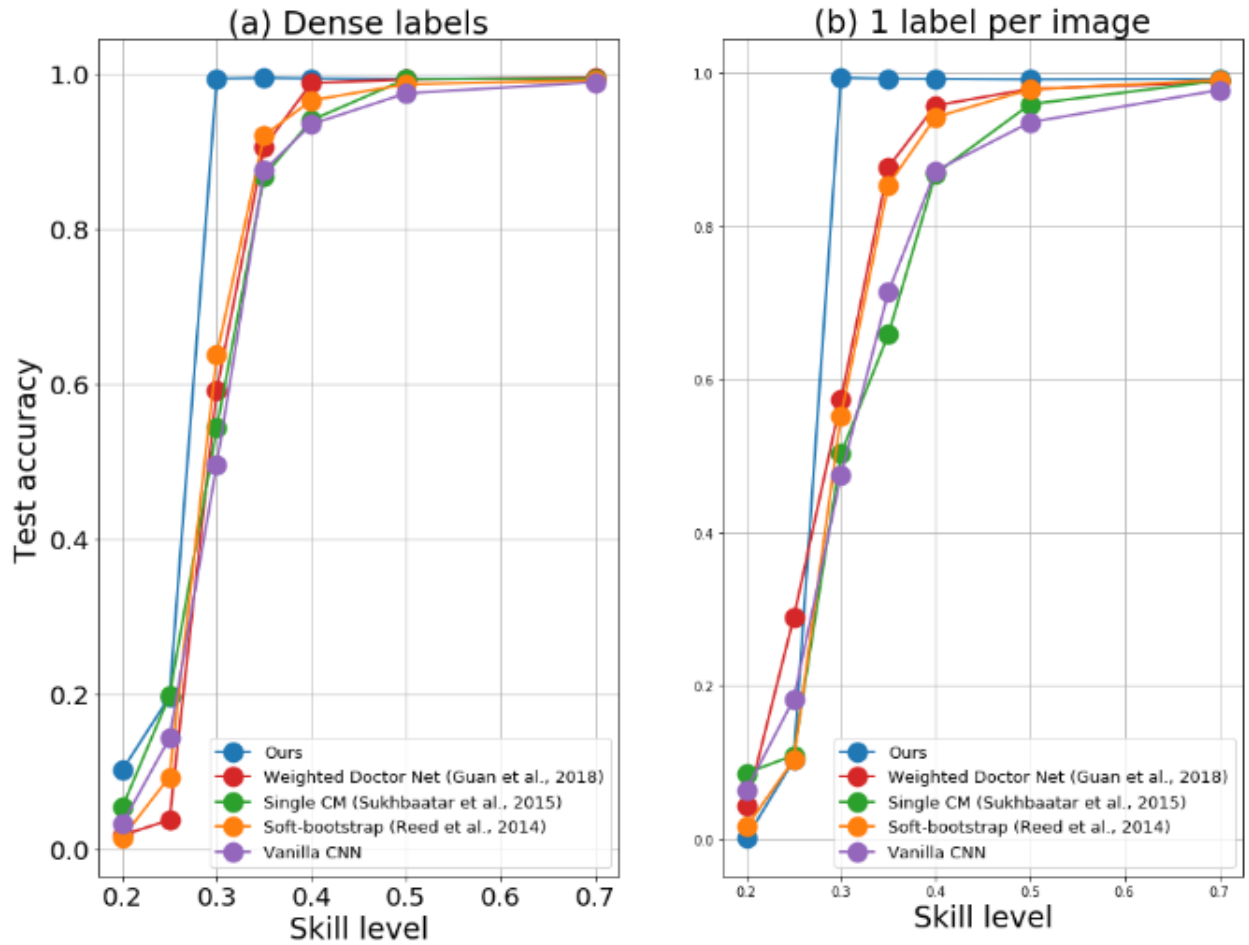

Figure 6: Classification accuracy on MNIST of different noise-robust models as a function of the mean annotator skill level p in two cases. Here, for each mean skill-level p , a group of 5 “pair-wise flippers” is formed and used to generate labels. (a). each example receives labels from all the annotators. (b). each example is labelled by only 1 randomly selected annotator.

实验4：真实实验（关于心脏的超声波图找了4位标注者）

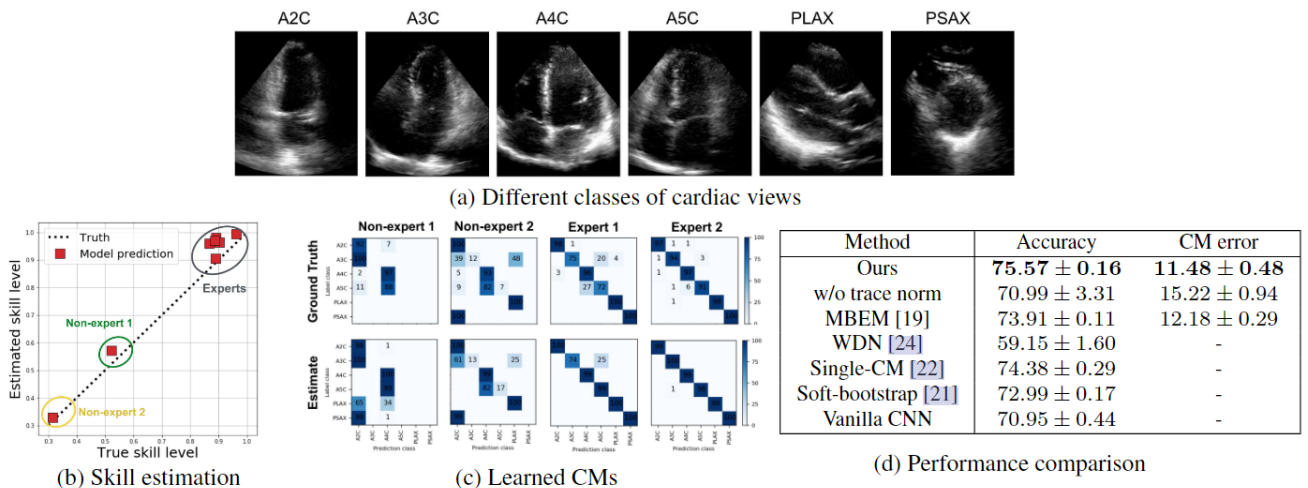

Figure 7: Results on the cardiac view classification dataset: (a) illustrates examples of different cardiac view images. (b) plots the estimated skill level of each annotator (average of the diagonal elements of its estimated CM) against the ground truth (c) compares the estimated CMs of the two least skilled and two most skilled annotators according the GT labels (d) summarizes the classification accuracy and error of CM estimation for different methods.
